In this study, $\text{LiMn}_{0.8}\text{Fe}_{0.2}\text{PO}_4$ and $\text{Li}(\text{Ni}_{0.5}\text{Mn}_{0.3}\text{Co}_{0.2})\text{O}_2$ thin film were selected to research. The low electronic conductivity and Li^+ diffusivity of LiMnPO_4 severely limits its electrochemical activity room for maneuver, especially under high current density. On the other hand, $\text{Li}(\text{Ni}_{0.5}\text{Mn}_{0.3}\text{Co}_{0.2})\text{O}_2$ can exhibit a promising electrochemical performance among currently working cathode materials. However, the Ni/Li mixing and growth of preferred orientation seriously affect the capacity and rate capability. To overcome these drawbacks, DC/RF magnetron sputtering approach will be incorporated. Through intrinsic modification of LiMnPO_4 cathode with Fe and C, a better electrochemical performance could be demonstrated in half lithium-ion battery. For layered type material, the $\text{Li}(\text{Ni}_{0.5}\text{Mn}_{0.3}\text{Co}_{0.2})\text{O}_2$ is deposited on various buffer layer substrate by reactive magnetron sputtering using single NMC target in an argon/oxygen atmosphere. It is expected that the development of $\text{LiMn}_{0.8}\text{Fe}_{0.2}\text{PO}_4$ and $\text{Li}(\text{Ni}_{0.5}\text{Mn}_{0.3}\text{Co}_{0.2})\text{O}_2$ would exhibit a great potential to meet the demand of next-generation high power Li-ion battery.
